Homogenous Products

C.Conlon

Grad IO

Introduction

One of the earliest exercises in econometrics is the estimation of supply and demand for a homogenous product

- ▶ According to Stock and Trebbi (2003) IV regression first appeared in a book by Phillip G. Wright in 1928 entitled *The Tariff on Animal and Vegetable Oils* [neatly tucked away in Appendix B: Supply and Demand for Butter and Flaxseed.]
- ▶ Lots of similar studies of simultaneity of supply + demand for similar agricultural products or commodities.

Working (1927)

Supply and Demand For Coffee, everything is linear

$$\begin{aligned} Q_t^d &=& \alpha_0 + \alpha_1 P_t + U_t \\ Q_t^s &=& \beta_0 + \beta_1 P_t + V_t \\ Q_t^d &=& Q_t^s \end{aligned}$$

Solving for P_t, Q_t :

$$P_t = \frac{\beta_0 - \alpha_0}{\alpha_1 - \beta_1} + \frac{V_t - U_t}{\alpha_1 - \beta_1}$$

$$Q_t = \frac{\alpha_1 \beta_0 - \alpha_0 \beta_1}{\alpha_1 - \beta_1} + \frac{\alpha_1 V_t - \beta_1 U_t}{\alpha_1 - \beta_1}$$

Price is a function of both error terms, and we can't use a clever substitution to cancel things out.

Working (1927)

To make things really obvious:

$$\begin{aligned} Cov(P_t, U_t) &= -\frac{Var(U_t)}{\alpha_1 - \beta_1} \\ Cov(P_t, V_t) &= \frac{Var(V_t)}{\alpha_1 - \beta_1} \end{aligned}$$

 $\textbf{When demand slopes down } (\alpha_1 < 0) \text{ and supply slopes up } (\beta_1 > 0) \text{ then price is positively correlated with demand shifter } U_t \text{ and negatively correlated with supply shifter } V_t.$

Working (1927)

$$\begin{array}{lcl} Cov(P_t,Q_t^d) & = & \alpha_1 VarP_t + Cov(P_t,U_t) \\ Cov(P_t,Q_t^s) & = & \beta_1 VarP_t + Cov(P_t,V_t) \\ \operatorname{mand}) Bias(\alpha_t) & = & \frac{Cov(P_t,U_t)}{Cov(P_t,U_t)}. \end{array}$$

- \blacktriangleright Bias in OLS estimate (Demand) $Bias(\alpha_1) = \frac{Cov(P_t, U_t)}{VarP_t}.$
- \blacktriangleright Bias in OLS estimate (Supply) $Bias(\beta_1) = \frac{Cov(P_t,V_t)}{VarP_t}.$
- $lackbox{We can actually write both this way when } Cov(U_t,V_t)=0$:

$$\text{OLS Estimate } = \frac{\alpha_1 Var(V_t) + \beta_1 Var(U_t)}{Var(V_t) + Var(U_t)}$$

- lacksquare More variation in supply $V_t o$ better estimate of demand.
- \blacktriangleright More variation in demand $U_t \to {\rm better}$ estimate of supply.
- ▶ Led Working to say the statistical demand function (OLS) is not informative about the economic demand function (or supply function).

Simultaneity

- ▶ For most of you, this was probably a review.
- ▶ We know what the solution is going to be to the simultaneity problem.
- ▶ We need an excluded instrument that shifts one curve without affecting the other.
- ▶ We can use this to form a 2SLS estimate.
- ▶ Instead let's look at something a little different...

Simultaneity and Identification

Angrist, Imbens, and Graddy (ReStud 2000).

- ▶ Demand for Whiting (fish) at Fulton Fish Market
- ▶ Do not place functional form restrictions on demand (log-log, log-linear, linear, etc.).
- lacktriangleright "What does linear IV regression of Q on P identify, even if the true (but unknown) demand function is nonlinear"
- Takes a program evaluation/treatment effects approach to understanding the "causal effect" of price on quantity demanded.
- ▶ Aside: Is there even such a thing as the causal effect of price on quantity demanded?

Four Cases

Ranked in increasing complexity

1. Linear system with constant coefficients

$$\begin{array}{lcl} q_t^d(p,z,x) & = & \alpha_0 + \alpha_1 p + \alpha_2 z + \alpha_3 x + \epsilon_t \\ q_t^s(p,z,x) & = & \beta_0 + \beta_1 p + \beta_2 z + \beta_3 x + \eta_t \end{array}$$

2. Linear system with non-constant coefficients

$$\begin{array}{lcl} q_t^d(p,z,x) & = & \alpha_{0t} + \alpha_{1t}p + \alpha_{2t}z + \alpha_{3t}x + \epsilon_t \\ q_t^s(p,z,x) & = & \beta_{0t} + \beta_{1t}p + \beta_{2t}z + \beta_{3t}x + \eta_t \end{array}$$

3. Nonlinear system with constant shape (separable)

$$q_t^d(p, z, x) = q^d(p, z, x) + \epsilon_t$$

$$q_t^s(p, z, x) = q^s(p, z, x) + \eta_t$$

4. Nonlinear system with time-varying shape (non-separable)

$$q_t^d(p, z, x) = q^d(p, z, x, \epsilon_t)$$

$$q_t^s(p, z, x) = q^s(p, z, x, n_t)$$

AIG: Heterogeneity

Two kinds:

- 1. Heterogeneity depending on value of p fixing t (only relevant in nonlinear models)
- 2. Heterogeneity across t, fixing p (cases 2 and 4).
- ▶ The problem is that we don't generality know which kind of heterogeneity we face.
- ▶ Is case (4) hopeless? Or what can we expect to learn?
- ▶ Even econometricians struggle with non-linear non-separable models (!)

AIG: Assumptions

Assume binary instrument $z_t \in \{0,1\}$ to make things easier.

- 1. Regularity conditions on $q_t^d, q_t^s, p_t, z_t, w_t$ first and second moment and is stationary, etc.
 - $q_t^d(p,z,x)$, $q_t^s(p,z,x)$ are continuously differentiable in p.
- 2. z_t is a valid instrument in q_t^d
 - ullet Exclusion: for all p,t

$$q_t^d(p,z=1,x_t) = q_t^d(p,z=0,x_t) \equiv q_t^d(p,x_t)$$

ie: conditioning on \boldsymbol{p}_t means no dependence on \boldsymbol{z}_t

- Relevance: for some period t: $q_t^s(p_t,1,x_t) \neq q_t^s(p_t,0,x_t)$. ie: z_t actually shifts supply somewhere!
- Independence: ϵ_t, η_t, z_t are mutually independent conditional on x_t .

Wald Estimator

Focus on the simple case:

- $lackbox{} z \in \{0,1\}$ where 1 denotes "stormy at sea" and 0 denotes "calm at sea"
- ▶ Idea is that offshore weather makes fishing more difficult but doesn't change onshore demand.
- lacktriangle Ignore x (for now at least) or assume we condition on each value of x.

$$\hat{\alpha}_{1,0} \rightarrow^p \frac{\mathbb{E}[q_t|z_t=1] - \mathbb{E}[q_t|z_t=0]}{\mathbb{E}[p_t|z_t=1] - \mathbb{E}[p_t|z_t=0]} \equiv \alpha_{1,0}$$

- lacksquare If we are in case (1) then we are good. In fact, any IV gives us a consistent estimate of $lpha_1$
- lacktriangle If we are in case (4) then $lpha_{1,0}$ the object we recover, is not an estimator of a structural parameter.
- Moreover, this is at best a LATE, and thus it differs depending on which instrument we use!

AGI: Negative Results

- ▶ Should we divorce structural estimation from estimating "deep" population parameters (as suggested by Lucas critique)?
- ightharpoonup Authors make the point that IV estimator identifies something about relationship between p and q, without identifying deep structural parameters?
- ▶ In IO this is a somewhat heretical idea (especially to start the course with).

AGI: Structural Interpretation

In order to interpret the Wald estimator $\alpha_{1,0}$ we make some additional economic assumptions on the structure of the problem:

- 1. Observed price is market clearing price $q_t^d(p_t)=q_t^s(p_t,z_t)$ for all t. (This means no frictions!).
- 2. "Potential prices": for each value of \boldsymbol{z} there is a unique market clearing price

$$\forall z,t: \tilde{p}(z,t) \text{ s.t. } q_t^d(\tilde{p}(z,t)) = q_t^s(\tilde{p}(z,t),z).$$

 $\tilde{p}(z,t)$ is the potential price under any counterfactual $\left(z,t\right)$

AGI: Structural Interpretation

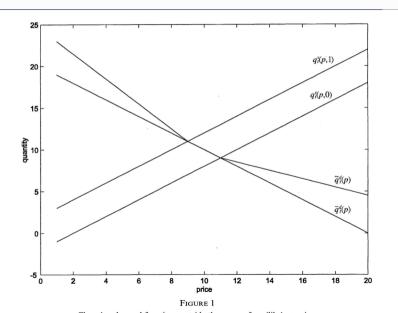

- lacksquare Just like in IV we need denominator to be nonzero so that $E[p_t|z_t=1] \neq E[p_t|z_t=0].$
- ▶ Other key assumption is the familiar monotonicity assumption
 - $\tilde{p}(z,t)$ is weakly increasing in z.
 - Just like in program evaluation this is the key assumption. There it rules out "defiers" here it allows us to interpret the average slope as $\alpha_{1,0}$.
 - Assumption is untestable because you do not observe both potential outcomes $\tilde{p}(0,t)$ and $\tilde{p}(1,t)$ (same as in program evaluation).
 - Any story about IV is just a story! (Always the case!) unless we have repeated observations on the same individual.

The key result establishes that the numerator of $\alpha_{1,0}$:

$$\mathbb{E}[q_t|z_t=1] - \mathbb{E}[q_t|z_t=0] = \mathbb{E}_t \left[\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} d\, s \right]$$

- For each t we average over the slope of demand curve among the two potential prices: $\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} d\ s$
- ightharpoonup This range could differ for each t.
- ▶ Then we average this average over all *t*.

AGI: Figure

AGI: Takeaways

What did we learn?

- lacktriangledown $lpha_{1,0}$ only provides information about demand curve in range of potential price variation induced by the instrument.
- ▶ Don't know anything about demand curve outside this range!
- For different instruments z, $\alpha_{1,0}$ has a different interpretation like the LATE does. (Different from the linear model where anything works!).
- ▶ This is a bit weird: different cost shocks could trace out different paths along the demand curve— why do we care if price change came from a tax change or an input price change? Are they tracing out different subpopulations?
- ▶ We need monotonicity so that we know the range of integration $\tilde{p}(0,t) \to \tilde{p}(1,t)$ instead of $\tilde{p}(1,t) \to \tilde{p}(0,t)$
- $lackbox{ Observations where } \tilde{p}(0,t) = \tilde{p}(1,t) \ {
 m don't\ factor\ into\ the\ average\ but\ we\ don't\ know\ what\ these observations\ are\ because\ potential\ prices\ are\ unobserved!\ What\ is\ the\ relevant\ sub-sample?$

AGI: Nonlinear IV

$$\begin{array}{lcl} \alpha_{1,0} & = & \frac{\mathbb{E}[\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} d\, s]}{\mathbb{E}\tilde{p}(1,t) - \mathbb{E}\tilde{p}(0,t)} \\ & \to & \int_0^{\infty} E\left[\frac{\partial q_t^d(s)}{\partial s} | s \in [\tilde{p}(0,t), \tilde{p}(1,t)]\right] \omega(s) ds \end{array}$$

- \blacktriangleright given t average the slope of q_t^d from $\tilde{p}(0,t)$ to $\tilde{p}(1,t)$
- $lackbox{ given price }s\in [\tilde{p}(0,t),\tilde{p}(1,t)] ext{ average }q_t^d(s) ext{ across }t. ext{ (randomness is due to }\epsilon_t).$
- $\blacktriangleright \ \ \text{Weight} \ \omega(s) \ \text{is not a function of} \ t \ \text{but it is largest for prices most likely to fall between} \ \tilde{p}(0,t) \\ \ \text{and} \ \tilde{p}(1,t).$
- $\begin{array}{c} \bullet \quad \text{Case (2): } q_t^d(p) = \alpha_{0t} + \alpha_{1t}p + \epsilon_t. \\ \\ \alpha_{1,0} = \frac{\mathbb{E}[\alpha_{1t}(\tilde{p}(1,t) \tilde{p}(0,t))]}{\mathbb{E}\tilde{p}(1,t) \mathbb{E}\tilde{p}(0,t)} \neq \mathbb{E}\alpha_{1,t}. \end{array}$

We need mean independence

AGI: Nonlinear IV

lacktriangle Suppose we had a continuous z instead, now we can do a full nonparametric IV estimator.

$$a(z) = \lim_{\nu \to 0} \frac{\mathbb{E}(q_t|z) - \mathbb{E}(q_t|z - \nu)}{\mathbb{E}(p_t|z) - \mathbb{E}(p_t|z - \nu)}$$

 \blacktriangleright Use a kernel to estimate $\hat{q}|z$ and $\hat{p}|z$

$$\alpha'(z) = \frac{\hat{q}'(z)}{\hat{p}'(z)} \approx \frac{\hat{q}'(z+h) - \hat{q}(z)}{\hat{p}'(z+h) - \hat{p}(z)}$$

AGI: Takeaways

- ▶ When you have a parametric model, you don't need these results because we can define whatever (nonlinear) parametric functional form we want.
- ► There we will focus on parsimonious and realistic parametric functional forms. (this is the rest of the course)
- ▶ If we don't have a parametric model, then these show us that linear IV estimators give us some average (a particular one!) of slopes.
- Caveat: this only works for a single product. In the multi-product case things are a lot more complicated
 - For multiproduct oligopoly it is much harder to satisfy the monotonicity condition. Why?
